

Website Risk Analysis – Results Explanation

Name: Arjun Kumar

1. Introduction

This project focuses on analyzing merchant websites to identify potential risk signals before onboarding.

The approach is based on rule-driven logic combined with basic external validation signals to simulate a real-world risk assessment system.

2. How the System Works

The system evaluates a website in four stages:

- First, it extracts key elements such as page content, links, and contact information
- Then, rule-based checks are applied to detect suspicious patterns like risky keywords or abnormal link counts
- Domain-level signals such as HTTPS usage and domain type are also evaluated
- Finally, external validation is simulated by checking the presence of negative indicators like “scam”, “fraud”, or lack of online footprint

Based on all these signals, a final risk score and decision are generated.

3. Website Analysis

Website 1: <https://manifestwaresoftware.com/web/>

Observations:

- The website has a structured layout with clear service-based content
- Contact-related information is present, indicating legitimacy
- Although the word “earn” appears, it is not used in a suspicious context
- The number of links is high (229), but consistent with a service-based website

- No negative external indicators were found

Evaluation:

- Suspicious Keyword → Low severity
- High Link Count → Medium (but contextually acceptable)
- External Signals → Clean

Final Result:

- Risk Score: 25–30
- Decision: ALLOW

Explanation:

Even though minor internal signals exist, the overall structure, content quality, and absence of negative external signals indicate that this is a legitimate business website.

Website 2: <https://zylotechindia.online/>**Observations:**

- The website has limited structured content
- The word “earn” appears in a more promotional context
- Domain uses “.online”, which is generally considered lower trust
- Contact and business identity signals are weak or unclear
- External presence is minimal

Evaluation:

- Suspicious Keyword → Medium severity
- Domain Type (.online) → Medium risk
- Weak Trust Signals → High risk

Final Result:

- Risk Score: 65–75
- Decision: BLOCK / REVIEW

Explanation:

Multiple moderate-to-high risk signals are present, especially weak trust indicators and domain credibility issues. Even without strong external fraud signals, the overall profile suggests a potentially risky merchant.

4. Conclusion

The system provides a simple but effective way to evaluate merchant risk using rule-based logic and basic external validation.

It helps in quickly identifying suspicious websites while allowing legitimate ones to pass.

5. Future Improvements

- Integrate real external APIs (Google Search, WHOIS)
- Improve keyword detection using context-aware logic
- Add domain age and reputation scoring
- Enhance decision accuracy with weighted scoring
