

Website Risk Analysis – Results Explanation

Name: Arjun Kumar

1. Introduction

This project is about analyzing websites to identify possible risk factors. The idea is to simulate a basic system that checks whether a merchant website looks safe or risky before onboarding.

Instead of using complex models, I used simple rule-based logic combined with some basic external checks.

2. How the System Works

The system works in a few steps:

- It first extracts text, links, and email information from the website
- Then it checks for certain patterns like suspicious keywords, number of links, etc.
- It also checks domain-related signals like domain type and HTTPS
- Finally, a simple external check is done by matching keywords like “scam”, “fraud”, or “review”

Based on all these, a final risk level is calculated.

3. Website Analysis

Website 1: <https://manifestwaresoftware.com/web/>

Observations:

- The word “earn” was found in the content, which is treated as a suspicious keyword
- The site has a very high number of links (229), which may indicate heavy promotions or redirections
- No negative keywords like scam or fraud were found in external check

Final Result: HIGH RISK

Explanation:

Even though there are no external negative signals, the internal indicators are quite strong. Especially the high number of links and presence of earning-related keywords make the website look slightly suspicious.

Website 2: <https://zylotechindia.online/>

Observations:

- The word “earn” was found in the content
- The site has a moderate number of links (84)
- The domain uses “. online”, which is considered less trustworthy
- No external negative keywords were found

Final Result: HIGH RISK

Explanation:

In this case, multiple risk factors are present.

The suspicious keyword and the domain type together increase the overall risk.

Even though external signals are clean, the internal and domain-level checks lead to a high-risk classification.

4. Conclusion

The system gives a simple way to analyze websites using basic rules.

It is not perfect, but it helps in identifying possible risks quickly.

The idea can be improved further by adding more advanced checks and better external validation.

5. Future Improvements

- Use real external data (like search APIs)
- Check domain age using WHOIS
- Improve keyword detection with better context
- Add more signals for better accuracy
